

CrispR analysis with Bioconductor

Jieun Jeong

2025-04-11

This vignette is based on a web page of Bioinformatics Resource Centre at Rockefeller University and it show how to use several Bioconductor packages in the analysis of data from a CrispR screen.

First steps

We start from setting the working directory and downloading the data if not downloaded already.

```
wd <- "/Users/jieun/Work/Crispr"
wdf <- function(...) file.path(wd,...)
Download <- function(url, filename) {
  file_path <- wdf(filename)
  if (file.exists(file_path))
    return()
  options(timeout = 1000)
  download.file(url, file_path)
  unzip(file_path,exdir = wd)
}
Download("https://github.com/LewisLabUCSD/PinAPL-Py/archive/master.zip",
         "pinaplData.zip")
Download("http://pinapl-py.ucsd.edu/example-data","TestData.zip")
dN <- wdf("New_Example_1580342908_4/Analysis")
Download("http://pinapl-py.ucsd.edu/run/download/example-run","Results.zip")
```

Quality control of fastq data

We may inspect several metrics of data quality. For larger data sets, we use random sampling that yields sufficiently accurate results, while time consuming steps may be avoided if data has clearly low quality.

```
require(ShortRead)
CRfile <- wdf("PinAPL-Py-master/Data/Tox-A_R01_98_S2_L008_R1_001_x.fastq.gz")
fqSample <- FastqSampler(CRfile,n=10^5)
fastq <- yield(fqSample)
fastq # check sample statistic
```

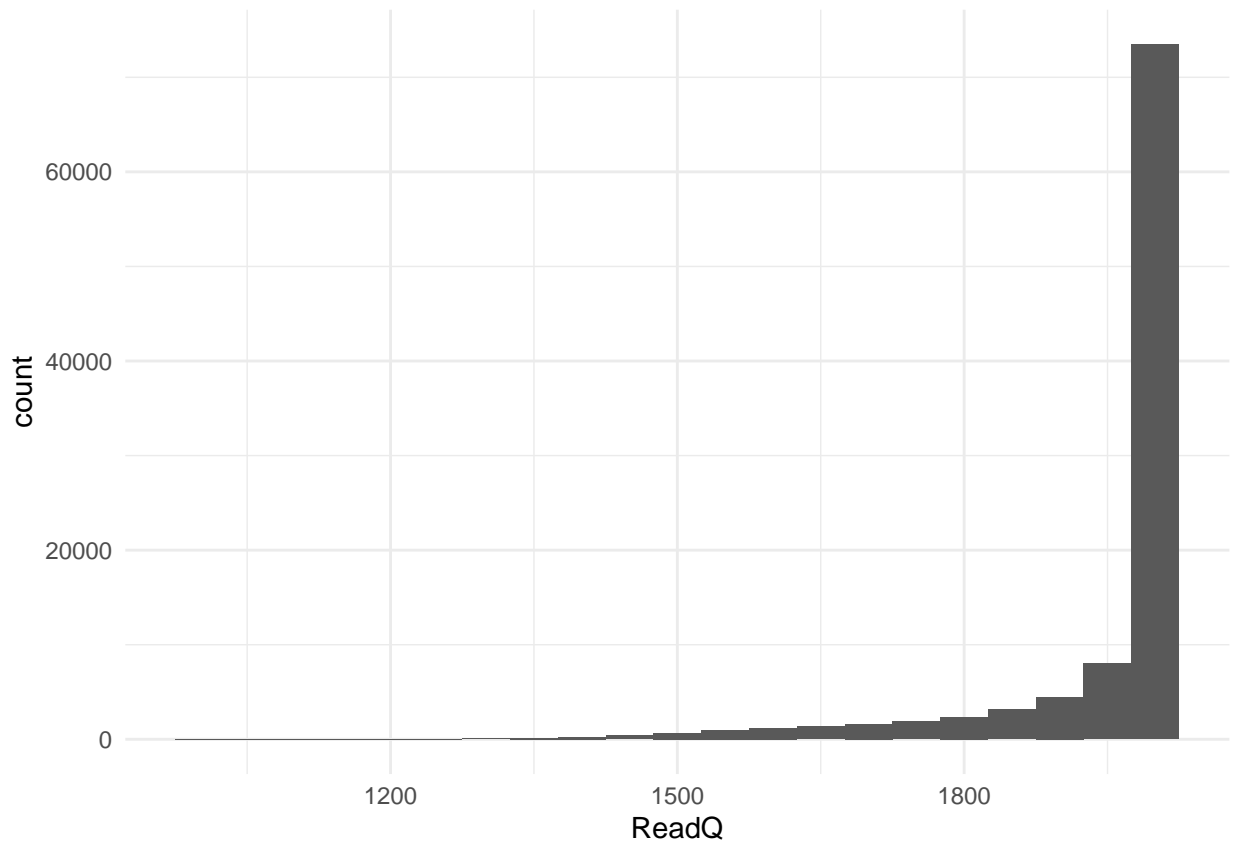

```
## class: ShortReadQ
## length: 100000 reads; width: 50 cycles
```

Now we use so-called accessor functions. The choice of bin width corresponds to the average bin quality rounded down to integer.

```
readQuality <- quality(fastq)
readQualities <- alphabetScore(readQuality)
readQualities[1:14]
```

```
## [1] 1282 2016 1095 2016 2020 2016 1875 2020 2011 2020 1422 2020 1235 2020
```

```
require(ggplot2)
toPlot <- data.frame(ReadQ=readQualities)
ggplot(toPlot,aes(x=ReadQ))+geom_histogram(binwidth=50)+theme_minimal()
```

Q40 quality can be optimistic, so other measures can be more reliable, like how close the distribution of nucleotides on read position is close to what we can expect.

```
readSequences <- sread(fastq)
readSequences_AlphFreq <- alphabetFrequency(readSequences)
readSequences_AlphFreq[1:3,]
```

```
##      A  C  G  T  M  R  W  S  Y  K  V  H  D  B  N  -  +  .
## [1,] 16 10 12 12 0 0 0 0 0 0 0 0 0 0 0 0 0 0
## [2,] 14 15 13  8 0 0 0 0 0 0 0 0 0 0 0 0 0 0
## [3,] 16 15 11  8 0 0 0 0 0 0 0 0 0 0 0 0 0 0
```

```
readSequences_AlphbyCycle <- alphabetByCycle(readSequences)
readSequences_AlphbyCycle[1:4,1:10]
```

```
##      cycle
## alphabet [,1] [,2] [,3] [,4] [,5] [,6] [,7] [,8] [,9] [,10]
##      A    77 1594 1871 96556 96304    59    42    33    36    56
##      C   1762 96500 1589   104  1609  1903 96355    69    62    32
##      G   1543 1805 96400 1751   143    34    97  1587  2085 97832
##      T  94787   101   140  1589  1943 98004  3506 98311 97817  2080
```

We can use barplot to visualize the distribution of the read frequencies. We see the reads have a constant prefix used to precipitate selectively DNA with guiding sequences, and a variable part, guiding sequences themselves, and effects of contamination as minorities in the prefix.

```
counts <- readSequences_AlbyCycle[1:4,1:50]
barplot(counts, col = c("blue", "red", "green", "yellow"),
        legend.text = rownames(counts),
        args.legend = list( x = "topright", inset = c(-0.068, 0)),
        main = "Nucleotide Counts by Cycle",
        names.arg = 1:50)
```

The initial cycle may be affected by low quality rather than contamination, that can be checked as follows

```
qualAsMatrix <- as(readQuality,"matrix")
toPlot <- colMeans(qualAsMatrix)
plot(toPlot, xlab = "cycle", ylab = "Q40")
```

The conclusion here is that quality is fine, but in mapping tolerating one mismatch and trimming first two cycles can be considered.

Aligning single data file

The further analysis requires to align reads to the sgRNA require to quantify sgRNA abundance in our samples. We start by retrieving and indexing the reference.

```
GeCKO <- read.delim(wdf("PinAPL-py_demo_data/GeCKOv21_Human.tsv"))
GeCKO[1:2,]
```

```
##   gene_id      UID      seq
## 1   A1BG HGLibA_00001 GTCGCTGAGCTCCGATTCTGA
## 2   A1BG HGLibA_00002 ACCTGTAGTTGCCGGCGTGC
```

```
require(Biostrings)
sgRNAs <- DNASTringSet(GeCKO$seq)
names(sgRNAs) <- GeCKO$UID
writeXStringSet(sgRNAs, file=wdf("GeCKO.fa")) # sgRNA reference
Index <- wdf("GeCKO")
Index.fa <- paste0(Index, ".fa")
require(Rsubread)
buildindex(Index, Index.fa, indexSplit=FALSE)
```

```
##
```

```

## ||
## || Total reads : 500,000 ||
## || Mapped : 413,480 (82.7%) ||
## || Uniquely mapped : 413,480 ||
## || Multi-mapping : 0 ||
## ||
## || Unmapped : 86,520 ||
## ||
## || Indels : 0 ||
## ||
## || Running time : 2.2 minutes ||
## ||
## \\=====//
```

We got 82.7% of uniquely mapped reads, we can test what happens if we allowed number a mismatch by setting `maxMismatches = 1`. It increases the number of mapped reads by 8000, i.e. 1.6%. However, the reference has sequences of length 20, so the constant prefix is soft-clipped, and one mismatch among 20 or 19 may create data noise that could significantly affect some genes associated with the guiding sequences in the reference.

Quantifying alignment result for a collection of data files

To process bam files we will use packages that work with bam format without decompressing it into sam format. The scheme is that we create a vector of fastq files for samples in a CRISPR screen project, and then this vector together with the reference of gRNAs used in the project we create a data frame of counts. For reasons we will see later we do it for two examples.

```
# Files of PinAPL demo
d <- wdf("PinAPL-Py-master/Data/*fastq.gz")
Files <- Sys.glob(d)
```

Then we apply a “data frame maker” that can be used in other projects too.

```

require(GenomicAlignments)
Files_2_DF <- function(Files,indexFile) {
  f_no <- length(Files)
  for (i in seq(1,f_no)) {
    fi <- Files[i]
    # co <- CrisprCounts(fi,Index)
    output <- sub("\\.f[^.]*\\.gz$", ".bam", Files[i])
    align(indexFile, Files[i], output_file=output, nthreads=4, unique=TRUE,
          nBestLocations=1, type = "DNA", maxMismatches = 0, TH1=1)
    # We decided to be most conservative and require that all 20 nucleotides of
    # gRNAs are in the alignment, but one can use different criteria too.
    temp <- readGAlignments(output)
    # temp <- temp[width(temp) == 20]
    co <- data.frame(table(seqnames(temp)),row.names = "Var1")
    if (i == 1)
      DF <- co
    else
      DF <- cbind(DF,co)
  }
  return(DF)
}

```

Now we use that code

```
Counts <- Files_2_DF(Files,Index)
```

```

```

Now we can apply DESeq to find differential guides and genes.

```
require(DESeq2)
useCol <- DataFrame(Group=factor(c("C", "C", "TA", "TA", "TB", "TB"),
                                levels = c("C", "TA", "TB")), row.names = colnames(Counts))
dds <- DESeqDataSetFromMatrix(Counts, colData = useCol, design = ~Group)
dds <- DESeq(dds)
TAvsC <- results(dds, contrast=c("Group", "TA", "C"))
TAvsC <- TAvsC[order(TAvsC$pvalue),]
head(TAvsC)
```

```
## log2 fold change (MLE): Group TA vs C
## Wald test p-value: Group TA vs C
## DataFrame with 6 rows and 6 columns
##           baseMean log2FoldChange    lfcSE      stat      pvalue      padj
##           <numeric>    <numeric> <numeric> <numeric>    <numeric> <numeric>
## HGLibB_44908    584.528      10.06356    2.34056    4.29964 1.71079e-05 0.773168

## HGLibB_23505    159.617       9.73169    2.72577    3.57025 3.56642e-04 0.773168
```

Note that fold changes of top gRNA's are "decent" but adjusted p-values are not. Later we will see the reason. In general, DESeq is not recommended for CRISPR screens because interpretation of the read counts is different, we want to know essential genes in the screen context, not "differentially expressed". Thus we will try to apply recommended

```
require(CRISPRcleanR)
data(GeCKO_Library_v2) # GeCKO reference processed for use with CRISPRcleanR
```

With CRISPRcleanR (ccr from now) annotation for our CRISPR platform, we edit Counts to Counts.ccr, a format required by ccr. Some sgRNA rows will be removed, 1000 of them are for control sgRNAs, and a few for genes. The issue of annotating sgRNAs for those genes will be left for later and now we will remove them from consideration:

```
Counts.ccr <- Counts[rownames(GeCKO_Library_v2),]
Counts.ccr <- cbind(GeCKO_Library_v2[,c("CODE", "GENES")], Counts.ccr)
#normANDfcs<-ccr.NormfoldChanges(Dframe=Counts.ccr, min_reads=10,
#                                display=TRUE, saveToFig=FALSE,
#                                libraryAnnotation = GeCKO_Library_v2,
#                                ncontrols = 2)
```

It does not work. Probably the issue lies in very poor correlation of control samples, i.e. 0.13, compared to correlations within other pairs of replicates, 0.96 and 0.999.

```
cor(Counts.ccr[,3:8])
```

```
##           Contr_1    Contr_2    ToxA_1    ToxA_2    ToxB_1    ToxB_2

```

To study subsequent steps in the analysis, we consider another data set

```
data(KY_Library_v1.0) # sequence ids, annotations, sequence
d <- file.path(system.file("extdata", package = "CRISPRcleanR"), "*fq.gz")
# decided to work in my directory
d <- wdf("KY_extdata/*gz")
Files <- Sys.glob(d)
basename(Files)
```

```
## [1] "test_plasmid.fq.gz" "test_sample1.fq.gz" "test_sample2.fq.gz"
```

```
d <- file.path(system.file("data",package = "CRISPRcleanR"))
data("KY_Library_v1.0.RData")
# create fasta of sequences in KY_Library_v1.0 and build the index
Index <- wdf("KY_Index")
Index.fa <- wdf("KY_Index.fa")
tempDF <- data.frame(ID = rownames(KY_Library_v1.0), seq = KY_Library_v1.0$seq)
faEntries <- paste0(">", tempDF$ID, "\n", tempDF$seq)
writeLines(faEntries,wdf("KY_Index.fa"))
buildindex(Index,Index.fa, indexSplit=FALSE)
```

```

```

```

colnames(Counts) <- c("Control", "Sample1", "Sample2")
Counts$gene <- KY_Library_v1.0$GENES
Counts <- Counts[,c(length(Files)+1, 1:length(Files))]
Counts <- tibble::rownames_to_column(Counts, var="sgRNA")
write.table(Counts, wdf("KY_Counts"), sep='\t', quote=FALSE, row.names=F)

```

Testing Files_2_DF and the second data set was very helpful, because the code was corrected: fastaq file have two possible suffices: .fq and .fastaq and converting the name to the name of .bam file had to be altered.

Finding essentiality (loss of fitness) and gain of fitness

The goal of CRISPR screen is to identify two types of interesting genes. The loss of fitness genes (in extreme case, essential) have smaller counts in knockout sample compared with control, and gain of fitness genes,

have larger count. In tumors, the latter may be tumor supresing genes, typically, few but of special interest in designing therapies.

Without normalization, fold changes may have show artifacts caused by several mechanism, for that reason packages like CRISPRcleanR can be used to remove them, e.g. using the following function

```
ccr.AnalysisPipeline(  
  file_counts = wdf("KY_Counts.tsv"),  
  outdir= wdf("KY_pipeline/"),  
  EXPname = "KY",  
  library_builtin = "KY_Library_v1.0",  
  run_mageck = FALSE,  
  ncontrols = 1  
)

## Error in value[[3L]](cond): ERROR: 3 | TYPE: CLIENT | MSG: Error in (function (counts, libraryAnnota  
## in step Check Library/Count data
```

This does not work either, this data set fails the requirement that 80% of the library sgRNA has at least 30 reads in control, instead, the largest number (instead of 30) that satisfies this condition is 5, too little for a reasonable null model. This tells that a good quality control has at least 6 million reads, although if the counts is a bit smaller, we can reduce the threshold from 30 to 25 or 20. So we try another data set

```
fn <- file.path(
system.file("extdata", package = "CRISPRcleanR"), "HT-29_counts.tsv"
)
ccr.AnalysisPipeline(
  file_counts = fn,
  outdir=wdf('./HT29_pipeline/'), EXPname = 'HT29',
  library_builtin = "KY_Library_v1.0",
  run_mageck = FALSE,
  ncontrols = 1
)
